DOs and DON'Ts in case of a snake bite in Zambia

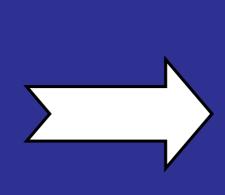

Zambia is home to 101 species of snakes. 30 of which can give you a dangerous venomous bite.

There is much misinformation on the internet about snakebite treatment in Africa.

This poster provide information on first aid in snakebites in Zambia.

In case of a snakebite, time is of the essence

The shorter the time between the bite and proper treatment at a health facility, the higher the chance of survival!

Follow this protocol in any snakebite case

KEEP VICTIM CALM - CONTACT AN EXPERT - TRANSPORT TO HOSPITAL - IMMOBILISE AND ELEVATE LIMB

RULE 1:

NEVER DO THIS:

RULE 2:

ALWAYS DO THIS:

1. Don't waste time!

If the snake is already dead or if it is safe to do so: make a photo of the snake so that snake experts can identify it. But: don't waste time!

The experts can advise on treatment based on the symptoms.

2. Don't apply any of the methods below:

Don't cut or suck the bite site

Don't apply electricity

Don't apply or give alcohol

Don't treat the bite site with heat or cold treatment

Don't apply any traditional medication

Don't apply anti-venom as a first aid measure

Don't apply tourniquet unless advised by a snakebite expert

All these measures do <u>nothing</u> to neutralise the venom but they waste time!

1. Calm the bite victim down.

The calmer the victim is, the slower the venom spreads. 90% of bites occur in limbs, where it can't kill the victim. We want to keep the venom there. Reassure the victim, explain that most snakebites aren't deadly and that there is enough time to reach a health facility.

- 2. Call a snakebite expert (see box below)
- 3. Immediately bring the victim to a health facility

From the moment of the bite, transport to a health facility must be organised

4. Immobilise and elevate the bitten limb

The bitten limb must be elevated above heart level. This slows the venom spreading down. Unless an expert has instructed otherwise, keep the limb still, because movement helps in spreading the venom.

5. Observe the victim and note symptom.

Symptoms may help the doctors give the right treatment. (time of the bite, dizziness, slurred speaking, swelling, pain at the bite site, etc.)

Where does the venom go?

<u>Popular belief:</u> most people believe venom goes into the **blood stream**. This is **wrong**.

In reality: usually venom is injected in muscles and absorbed by the lymphatic system.

The more you move, the quicker you pump the venom from this system to the blood stream and the vital organs, where it can become life-threatening.

(An exception is the venom of the Black mamba, which can enter the blood vessels as well as the lymphatic system).

After injection, venom spreads through your tissue. It is impossible to suck it out!

Traditional medication

Many believe in the effectiveness of traditional medication in snakebite treatment.

Unfortunately, THEY DO NOT WORK!!

Bringing a victim to a traditional healer wastes valuable time.

In addition:

Traditional healers work in a nonsterile environment with non-sterile instruments and materials. Treating a snakebite victim in such an environment leads to additional problems, such as infections.

Venom in the eye

Venom in the eye *without* a bite on the body is

NOT life-threatening!

And:

It does **not** require anti-venom.

Do the following:

- 1) **Immediately** rinse eye with running water for 15-20 minutes
- 2) Have the eye checked by a doctor
